

## Thermoelectric Sample Conditioner System (TESC-2983)

### FULLY AUTOMATED ASTM D2983 CONDITIONING AND TESTING ON THE CANNON® TESC SYSTEM WHITE PAPER

A critical performance parameter for transmission, gear, and hydraulic lubricants is low temperature viscosity. ASTM D2983<sup>1</sup> provides a procedure and specifications for measuring the low temperature viscosity of lubricants (Brookfield Viscosity<sup>2</sup>). The first edition of this method specified a refrigerated, forced-air cabinet for low temperature conditioning and did not include a sample preheat process. The current preheat process was added to the method in the early 1980's.

Cannon Instrument Company has developed a fully automated Thermoelectric Sample Conditioner (TESC) System for D2983. With the incorporation of a Brookfield DV2T digital viscometer and thermoelectrically controlled sample chamber, the TESC System is the first instrument to automate the entire conditioning and testing process. This includes preheating, room temperature stabilization, cooling of the sample to test temperature<sup>3</sup>, and testing final viscosity of the conditioned sample. Automation lessens the hands-on time needed to prepare and run a D2983 viscosity test, reduces variability, and improves test precision.

#### Procedure

The CANNON TESC System uses ASTM D2983 method Procedure D. To reduce test variability, the TESC System automates or removes many of the steps required to transfer the sample between conditioning and testing processes. Automation occurs through use of a thermoelectrically controlled sample chamber that manages the sample, without operator intervention, throughout the conditioning and testing processes.

Using a calibrated TESC System, an operator runs a D2983 test as follows:

1. Auto-zero the Brookfield DV2T viscometer.
2. Measure 20 mL of sample into a 25 mm × 150 mm, rimless test tube.
3. Carefully place the test tube with the sample into the TESC sample chamber.
4. Attach a #4B2 spindle to the DV2T and lower the viscometer into the run position.
5. Launch both the temperature control program and the viscometer program.

Once the temperature control program starts, the TESC System heats the sample to the preheat temperature and maintains it at that temperature for the required time. The TESC System then cools the sample to room temperature at the same rate used to raise it to the preheat temperature, and then further cools the sample to the desired test temperature according to the equation in D2983 Annex A1. This controlled heating and cooling is critical to reducing variability.

<sup>1</sup> [ASTM D2983 Standard Test Method for Low-Temperature Viscosity of Lubricants Measured by Brookfield Viscometer \(http://www.astm.org/Standards/D2983.htm\)](http://www.astm.org/Standards/D2983.htm)

<sup>2</sup> Testing of the low temperature viscosity of lubricants is commonly referred to as a “Brookfield Viscosity” because the method was developed using Brookfield rotational viscometers.

<sup>3</sup> The cooling profile is described in Annex 1 of ASTM D2983.

Throughout the thermal conditioning process, the DV2T program records the temperature of the sample chamber while waiting to measure the viscosity. When thermal conditioning of the sample completes, the DV2T automatically measures the sample viscosity by stepping through the typical range of spindle speeds for the sample type or expected viscosity. This eliminates the need to run multiple tubes of a sample. Once the viscosity measurements finish, the TESC System returns the sample to room temperature, nominally 25 °C. Afterwards, the operator can review the data and enhance the digital record with notes and additional information. The TESC System comes with a set of thermal conditioning programs for all of the common specification test temperatures as well as certain OEM measurement and report requirements.

**Table 1: TESC-5133 Thermal Conditioning Programs**

Fluid	Preheat Temperature	Test Temperature
Low viscosity (ATF, hydraulic fluid)	50 °C	-10 °C
		-20 °C
		-30 °C
		-40 °C
High viscosity (gear oil)	90 °C	-12 °C
		-26 °C
		-40 °C

A spreadsheet is provided to enable users to create thermal conditioning programs for test temperatures other than those provided.

## Data

The data presented in Table 2 demonstrate extensive testing of ASTM Inter-Laboratory Crosscheck Program (ILCP) samples with the TESC system<sup>4</sup>. Data for both Automatic Transmission Fluid (ATF) and Gear Oil samples were obtained using two TESC preproduction systems incorporating a DV2T viscometer. Results were calculated as follows:

**Repeatability:** ATF repeatability was calculated using 32 repeat determinations of ILCP samples at the same spindle speed. Gear oil repeatability data was calculated based on four repeat determinations of ILCP samples at the same spindle speed.

The difference between two viscosity determinations for each ILCP sample, at a single speed on a single TESC system was divided by the average of the two to establish a “Repeatability %” for each sample/spindle speed. The “Repeatability %” for all samples/spindle speeds was then averaged and reported as “Average Comparison %” in Table 2. The standard deviation of the “Repeatability %” for all ILCP samples/spindle speeds was calculated and reported in Table 2 as “Standard Deviation, %” and represents an estimate of the variation in the “Repeatability %” for the TESC System.

**Reproducibility:** ATF reproducibility data represent 84 viscosity determinations made at the end of 42 tests on 13 ILCP samples. Gear oil reproducibility data represent 52 viscosity determinations made at the end of 18 tests on eight samples.

The difference between the single spindle speed TESC System viscosity determination of an ILCP sample and the sample’s accepted value at that speed (as established in the ILCP report) was divided by the average of the two to establish a “Reproducibility %” for each sample/spindle speed. The “Reproducibility %” for all samples/spindle speeds was then averaged and reported as the “Average Comparison %” in Table 2. The standard deviation of the

“Reproducibility %” for all ILCP samples/spindle speeds was calculated and reported in Table 2 as “Standard Deviation, %” and represents an estimate of the variation in the “Reproducibility %” for the TESC System.

**Table 2: ASTM ATF & GO ILCP Sample Data Summary**

Product	Temperature	Precision	Average Comparison, %	Standard Deviation, %
ATF	-40 °C	Repeatability	0.80	1.68
ATF	-40 °C	Reproducibility	2.79	3.55
Gear Oil	-26 °C	Repeatability	1.12	0.40
Gear Oil	-26 °C	Reproducibility	0.62	6.31

<sup>4</sup> For complete sample data sets, see Table 4 and Table 5.

Published precision for D2983 viscosity is shown in Table 3 compared to estimated TESC System precision<sup>a</sup>. The data suggests exceptional repeatability and reproducibility as compared to current D2983-09 and 2014 proposed values for gear oils and ATF<sup>5</sup>.

**Table 3: ASTM D2983 Precision**

ASTM D2983	2009 Current Standard	2014 Proposed Revision	TESC System Estimates <sup>a</sup>
Repeatability	3.4 %	13.78 %	2.7 %
Reproducibility	20.6 %	18.28 %	8.6 %

<sup>a</sup> Reproducibility and repeatability are estimated based data collected in two laboratories, on two TESC systems from eight samples (six ATF and two gear oil). While this does not meet ASTM precision statement calculation requirements, results are consistent with variance seen in the ILCP sample testing data for the TESC System.

## Discussion and Conclusion

As demonstrated in the data comparison between the TESC System and the method's published precision, the TESC System is capable of meeting reproducibility and repeatability requirements for ASTM D2983 for both gear oils and ATF. It is the first ASTM D2983 sample conditioning system that automates not only the low temperature portion of the thermal conditioning process, but also the preheat and room temperature stabilization steps. Because all conditioning steps are carried out with the sample in place in the sample chamber, the TESC System minimizes or eliminates many data quality issues associated with temperature fluctuation and sample disruption during D2983 conditioning and viscosity measurement; decreasing variability.

Like other conditioning options for D2983 Procedure D, the sample is cooled during low temperature conditioning according to the equation in D2983 Annex A1. However, the TESC System also incorporates programmed preheat and room temperature stabilization profiles to ensure samples experience exactly the same conditions throughout the entire conditioning process. Furthermore, because samples are not physically transported between each conditioning step and then to the viscometer, temperature fluctuation resulting from transport is effectively eliminated. This ensures more consistent thermal conditioning and a repeatable viscosity measurement temperature. Incorporation of a compact sample chamber, only slightly larger than the sample stator, creates a tightly controlled conditioning environment and minimizes concerns about variation in coolant circulation in the TESC System. In the run position, the DV2T viscometer completely covers the sample chamber and isolates it from ambient conditions throughout sample conditioning and testing to ensure consistent temperature control.

A reference standard run during instrument set up confirms appropriate instrument programming, calibration, and temperature control. Sample chamber temperatures are automatically measured by an integrated RTD temperature

sensor throughout the conditioning and testing process. The thermal conditioning history is included in the data file along with measured viscosity and can be obtained by the user after test completion.

In addition to advanced thermal control, elimination of the need for sample transport allows the TESC System to improve test precision through reduced sample disruption. The importance of minimizing sample disruption is specifically referenced in D2983 procedures. Attachment and positioning of the spindle during initial set up of the TESC System rather than immediately prior to the viscosity measurement also helps to lessen the impact of sample disruption on test results and enhance measurement precision. The sample remains undisturbed until testing is initiated.

Along with improvements in test precision and accuracy, the TESC System offers a number of advantages over alternative ASTM D2983 sample conditioning options. Automation of the entire conditioning and testing process reduces operator hands-on time and minimizes the opportunity for operator error in the testing procedure. Pre-programmed run profiles for typical gear oil and ATF viscosity ranges reduce set up time and ensure consistency in sample conditioning.

<sup>5</sup> For data, see Table 6 — ASTM Committee D02 Precision Evaluation.
